

iReNovo UI Review

Open items — the 5 points that are not fixed

Date: 2026-09-20 • Source: iReNovo_UI_Review_points.pdf • Repository: DRP-UI, branch **main**

The review listed 28 points. **23 are fixed and on main** (commits 8f5ad1d and efec67a). The 5 below are not, and each is blocked on someone outside the UI work: one is a product decision, four are backend defects that cannot be corrected in the frontend. Point 29 in the source list is blank.

#	Open item	Owner
4	Signup / forgot password / Help Center / Privacy / Terms — keep or remove	Product owner
12	TxKG progress line: "Propagating over the full knowledge graph from Colic..."	Backend
15	Target score exceeds 100	Backend
25	@curatex free-text instruction does not complete	Backend
26	RunnerError: no UniProt entry matched the whole sentence	Backend

Each item below states what was observed, what was found in the code, why it was not fixed on the UI side, and the specific question that has to be answered before it can be closed.

Point 4 — Signup, forgot password, Help Center, Privacy Policy, Terms of Service

Owner	Product owner
Type	Product decision — not a code defect
Status	Unchanged, awaiting a decision

What the review asked

"Signup, forgot password screens, Help center, privacy policy/terms of services — decision to keep or remove — if keeping screens for that."

What is actually in the code today

All of these controls are visible on the login screen and **none of them do anything**:

- **Forgot password** — the button calls `handleForgotPassword()`, which is an empty function with a commented-out `navigate("/forgot-password")` inside it. There is no such route.
- **Help Center, Privacy Policy, Terms of Service** — three buttons in the login footer with no `onClick` handler at all.
- **Signup** — there is no signup screen anywhere in the codebase, and no link to one. Accounts are created in the Cognito user pool.

Why it was not fixed

Both answers are legitimate and they lead to very different amounts of work. Deciding on the product's behalf would be guessing.

Decision	What it takes
Remove	Delete the four controls from the login footer and the remember/forgot row. Roughly an hour, no backend involvement.

Decision	What it takes
Keep	Build a forgot-password flow — AWS Amplify already supports this through <code>resetPassword()</code> and <code>confirmResetPassword()</code> , so it is a screen and a route rather than new infrastructure. Help Center, Privacy Policy and Terms of Service each need a route and, more importantly, someone to write the content. Signup additionally needs a decision on whether self-registration is allowed at all, which is a security question as much as a UI one.

Please confirm: keep or remove? If keeping — who supplies the Privacy Policy and Terms of Service copy, and is self-registration permitted?

Note: leaving them visible and dead is the one option that should not ship. A tester will raise it again every round, and a user who clicks “Forgot password?” and gets nothing has no way to recover an account.

Point 12 — “Propagating over the full knowledge graph from Colic...”

Owner	Backend — TxKG runner
Type	Backend defect or unclear copy
Status	Not reproducible from the frontend; no UI change possible

What the review asked

“Backend: Propagating over the full knowledge graph from Colic... Backend what does that mean in txkg.”

What was checked

This string does not exist anywhere in the frontend source. A full-text search of `src/` returns no match for “Propagating”. The frontend renders the runner’s progress line verbatim as it arrives from the job status response — it does not compose, translate or edit that text.

The word “Colic” is the part that needs explaining. It appears to be either a truncated disease label or a term the graph resolved to that does not match what the user submitted. Either way the decision is made server-side.

What is needed

From the backend team: which component emits this progress line, what “Colic” refers to when the submitted disease was something else, and whether the message is intended to be shown to researchers at all. If it is internal diagnostic text, it should not be returned in the user-facing progress field — and the frontend will render whatever replaces it without further changes.

Point 15 — Target score is more than 100

Owner	Backend — TxKG scoring
Type	Backend defect
Status	Deliberately not masked in the UI — see below

What the review asked

“Backend: score is more than 100 — needs correction.”

What was checked

Confirmed. The API returns raw scores above 100 — **176.6** appears in the current sample response. The frontend does not calculate scores; it only formats what it is given, in `src/workflow/txkgResult.js`:

```
export const formatScore = (value) => {
  const n = Number(value);
  if (!Number.isFinite(n)) return "-";
```

```
    return n.toFixed(2);  
};
```

It rounds to two decimal places so the right-aligned column stays straight. That is the whole of the frontend's involvement with the number.

Why it was not “fixed” in the UI

Clamping the display at 100 was considered and rejected. It would hide a real scoring-scale problem rather than solve it: the ranking would still be driven by the uncorrected values, and the numbers would become silently wrong instead of visibly wrong. A visibly wrong number gets reported, as it was here. A silently capped one does not.

What is needed

From the backend team: confirm the intended scale. If scores are meant to be 0–100, the normalisation is wrong upstream and needs correcting there. If the scale is genuinely unbounded, say so — the UI currently implies a percentage, and the column will be relabelled and the formatting adjusted to suit.

Points 25 and 26 — @curatex free-text instruction fails

Owner	Backend — CurateX runner / instruction parsing
Type	Backend defect
Status	UI workaround shipped; free-text path still broken

What the review reported

“Upon giving input @curatex create drug profile for JAK2 — CurateX could not finish”, with the error:

```
RunnerError: No reviewed human UniProt entry matched  
'Create drug profile for JAK2'. Use the gene symbol  
(e.g. 'JAK2') or the canonical protein name.
```

Root cause

The error text gives it away: the backend received **the entire sentence** as the target name and looked up “Create drug profile for JAK2” in UniProt. It did not extract the gene symbol from the instruction. The two review points are one defect — 25 is the symptom, 26 is the error it produces.

What the UI already does about it

Review point 24 asked for a way to move on from LitMineX without typing an @mention. That is built and shipped: a **Continue to CurateX** control that sends a structured selections payload containing the gene symbols. Because the target arrives as a field rather than as prose, that path **cannot** produce this error. Most users will never hit the problem again.

What is still broken

Typing the instruction as free text. The frontend cannot fix this without parsing biomedical instructions in the browser and second-guessing the agent — which would put gene-symbol extraction in two places and make the two disagree the first time either changed.

What is needed

From the backend team: extract the gene symbol from the instruction before the UniProt lookup, or — if free-text instructions are not meant to be supported — return an error that names what it expected, so the UI can show something better than a runner stack trace. Confirm which of the two, and the UI will be adjusted to match.

For reference: what is already done

23 of the 28 points are fixed and pushed to main. Points 1, 2, 3, 5, 6, 7, 8, 9, 10, 11 and 13 were changed in commit efec67a; points 14, 16, 17, 18, 19, 21, 22, 23, 24, 27 and 28 were fixed earlier in 8f5ad1d and re-verified line by line. Point 20 was half-done and is now complete.

These were verified by code inspection and a clean production build, not by an end-to-end run against the live backend. Points 17 to 28 depend on live API responses, so they need a QA pass on a deployed build before they are signed off.

The full point-by-point breakdown, including everything already fixed, is in REVIEW_FIXES.md in the repository root.
